

02

Organic Compounds
containing Nitrogen**Amines:**

Amines are derivatives of ammonia in which one or more hydrogen atoms are replaced by alkyl group(s). Amines are classified as primary, secondary and tertiary depending on the number of alkyl groups attached to nitrogen atom.

**General methods of preparation:****(1) Ammonolysis of alkyl halides and alcohols :**

From Ammonolysis of alkyl halides [Hofmann's ammonolysis] : When an aqueous solution of ammonia is heated with alkyl halide all the three types of amines and quaternary ammonium salt are formed.

If ammonia is taken in excess, 1° amine is the main product.

(2) Hoffmann Elimination:

Quaternary ammonium salts on heating with moist silver oxide give alkenes.

This E₂ elimination gives the less substituted alkene (Hofmann product) rather than the more substituted alkene (Saytzeff product). The alkyl group having maximum β-hydrogen gives the major alkene if R groups attached to nitrogen are different.

(3) By reduction :

This reaction (b) is called Mendius reaction.

The reduction of alkyl isocyanides gives secondary amines.

Sn/HCl is used in laboratory preparation

(4) By hydrolysis of :

(a) $\text{R}-\text{NC}$: Alkyl isocyanide undergoes hydrolysis with mineral acid and forms alkyl amine.

(b) RNCO : Alkyl isocyanate undergoes hydrolysis on heating with KOH and forms alkyl amine.

(5) By Hofmann's bromamide reaction (Hofmann's Hypobromite reaction): This is a general method for the conversion of alkanamides into primary amines having one less carbon.

Mechanism :

(6) From Grignard reagent : Alkyl magnesium iodide reacts with chloramine to yield alkyl amine.

(7) Gabriel phthalimide synthesis : Phthalimide is first treated with KOH to obtain potassium phthalimide which is then treated with alkyl iodide. Then alkyl phthalimide on hydrolysis yields alkylamine. This method is used in the formation of pure aliphatic primary amines.

Phthalic acid

* Aniline is not formed by this reaction.

(8) Curtius reaction :

(9) Schmidt reaction : In presence of conc. H_2SO_4 alkanolic acid reacts with hydrazoic acid (N_3H) followed by hydrolysis to yield alkylamine.

**GOLDEN KEY POINTS**

- Separation of 1°, 2° and 3° amines**

$\text{R}_4\text{N}^+\text{X}^-$ does not undergo distillation

Mixture of 1°, 2°, 3° amine can be separated by following methods.

(i) Fractional distillation : The mixture of amines may be separated by fractional distillation because their boiling points are quite different. It is used in industry.

(ii) Hinsberg method : In this method mixture of amines is separated by using benzene sulphonyl chloride (Hinsberg's reagent).

3° amine does not react with benzene sulphonyl chloride. (No ppt. formed)

Physical Properties:

- (i) CH_3NH_2 is gas and $\text{C}_2\text{H}_5\text{NH}_2$ is a volatile liquid.
- (ii) Higher amines have fishy smell.
- (iii) H-Bonding (weaker as compared to $\text{H}-\text{O}-\text{H}$).

In 3° amine (due to absence of H-atom) H-bonding is not possible.

- (iv) **Boiling point** : Due to weak intermolecular H-bonding the B.P. of 1° and 2° amines are lower than those of alcohols of comparable molecular weight. The boiling point of 3° amines which form no H-bonds are near to those of alkanes of comparable molecular weight.

Boiling point $\propto$ molecular weight

Order of B.P. : 1° amine > 2° amine > 3° amine
 so order of volatility : 3° amine > 2° amine > 1° amine

- (v) **Solubility** : Low molecular weight amines are soluble in water. The water solubility of amines decreases with increasing size of alkyl group.

Order of solubility $\longrightarrow$ p- amine > s- amine > t- amine

Chemical properties:

- (i) Basic character of amines is due to the presence of lone pair of electrons on the N - atom.
- (ii) Basic strength depends on electron donating tendency.
- (iii) Order of basic character in aqueous solution : $(\text{CH}_3)_2 \text{NH} > \text{CH}_3 \text{NH}_2 > (\text{CH}_3)_3 \text{N} > \text{NH}_3$
- $(\text{C}_2\text{H}_5)_2 \text{NH} > (\text{C}_2\text{H}_5)_3 \text{N} > \text{C}_2\text{H}_5 \text{NH}_2 > \text{NH}_3$

GOLDEN KEY POINTS

- Tertiary amine is less basic than secondary due to following reasons :
 - Steric hindrance** : In tertiary amines (R_3N), three alkyl groups attached to N are bulkier and as such exert steric hindrance.
 - Decrease in hydration** :

In tertiary amine

Protonated t-amine can form H-bonding with water molecule only at one point
[less stable]

In secondary amine

Protonated s-amine can form H bonding with water molecules at two points
(more stable)

Conjugate acid of 3° amine are less stable as compared to 2° amine due to low hydration so less basic.

- The basic strength of aniline is less than aliphatic amines as the lone pair of electron present on N-atom interacts with the delocalized π -orbital of benzene ring. Hence it is less available for protonation on N-atom.

(1) Reactions showing basic nature :

It reacts with acids to form salts.

Alkyl ammonium chloride

(Acidic salt)

- (2) Reaction with alkyl halides** : Alkyl amine reacts with alkyl halides and forms sec., ter. amines and quaternary ammonium salt.

- (3) Acetylation** : Acetylation takes place when alkyl amine combines with acetyl chloride or acetic anhydride.

(N-alkyl acetamide)

(N-alkyl acetamide)

(4) Benzoylation (Schotten Baumann reaction) :

- (5) **Acidic nature** : Amines are very weak acids only 1° and 2° amines show acidic nature with active metals.

- (6) **Reaction with Tilden reagent** :

- (7) **Reaction with aldehydes** :

- (8) **Carbylamine Reaction (Isocyanide test)** : When primary amine heated with chloroform and alc. KOH alkyl isocyanide is formed which has very bad smell.

This test is also given by aniline . This is a test for p- amines.

- (9) **Hofmann's mustard oil test** : When primary alkyl amine is heated with carbon disulphide and mercuric chloride alkyl isothiocyanate is formed which has smell like mustard oil.

- (10) **Reaction with HNO₂** :

- (a) Primary amines react with nitrous acid to produce nitrogen gas [seen as bubbles]

- (b) $\text{R}_2\text{NH} + \text{HNO}_2 \longrightarrow \text{R}_2\text{N-NO} + \text{H}_2\text{O}$

Dialkyl nitroso amine (Yellow oily layer)

- (c) $\text{R}_3\text{N} + \text{HNO}_2 \longrightarrow \text{R}_3\text{NHNO}_2^{\oplus}$ Trialkyl ammonium nitrite (Soluble in water)

- (11) **Reaction with Benzenesulphonyl chloride (Hinsberg's reagent)** :

Note: Hinsberg test is used to distinguish between primary, secondary and tertiary amines.

These days benzenesulphonyl chloride is replaced by p-toluenesulphonyl chloride (TsCl)

Points to Remember :

- (i) Nitrosoamines are carcinogens (Cancer causing agents)
- (ii) Amines can have chiral N-atom but cannot be resolved into enantiomeric forms because of rapid inversion of one enantiomeric form into the other.
- (iii) The mixture of 1°, 2°, 3° amines can be distinguished by Hofmann's test or Hinsberg's reagent or nitrous acid test.

Aniline (C₆H₅NH₂):

General Methods of Preparation

(1) Lab method:

(2) Industrial method :

(3) From Phenol :

(4) From benzamide (Hofmann's bromamide reaction):

(5) From benzoic acid (Schmidt reaction) :

(6) From Grignard reagent :

(7) From phenyl isocyanide :

Physical Properties:

- (i) Fresh, aniline is a colourless oily liquid. On standing the colour becomes dark brown due to action of air and light.
- (ii) It's B.P. is 183°C.
- (iii) It is heavier than water.
- (iv) It has characteristic unpleasant odour. It is toxic in nature.

Reactions due to —NH₂ group

- (1) **Basic nature** : Aniline is weak base but it forms salt with strong acids. It accepts a proton.

- (2) **Alkylation** : Aniline reacts with alkyl halides forming secondary, tertiary and quaternary ammonium salts depending on the concentration of alkyl halides.

- (3) **Acylation** : Aniline reacts with acid chlorides or anhydrides to form corresponding amides called anilides. [The reaction of C₆H₅NH₂ with benzoyl chloride is example of "**Schotten Baumann reaction**"]

- (4) **Carbylamine reaction** :

Note : (1) Intermediate species is dichloro carbene [:CCl_2].

(2) This is test of aniline and other primary amine, known as **Isocyanide test**.

- (5) **Hoffmann's mustard oil reaction** : When aniline is heated with alc. CS₂ and excess of HgCl₂ phenyl isothiocyanate having a characteristic smell of mustard oil is formed.

This is a test of aniline and other primary amines.

(6) **Reaction with aldehydes** : Aniline condenses with aldehydes to form schiff's base.

(7) **Reaction with Hinsberg's reagent** :

(8) **Diazotisation** : Diazotisation is a reaction in which ice cooled solution of aniline in an inorganic acid reacts with sodium nitrite solution leading to the formation of diazonium salt.

Benzene diazonium chloride is a useful synthetic reagent. It is used in the preparation of many organic compounds.

Azo Coupling:

Azo coupling is the most widely used industrial reaction in the production of dyes, lakes and pigments. Aromatic diazonium ions acts as electrophiles in coupling reactions with activated aromatics such as anilines or phenols. The substitution normally occurs at the para position, except when this position is already occupied, in which case ortho position is favoured. The pH of solution is quite important; it must be mildly acidic or neutral, since no reaction takes place if the pH is too low.

Mechanism of Azo Coupling:

- (1) **Halogenation** : In polar and nonpolar medium Chlorine and bromine react with aniline and form trichloro and tribromo aniline respectively.

Note : However, monobromo or chloro derivative of aniline can be prepared if -NH₂ group is first protected by acetyl group. Here the reactivity decreases due less +M effect on benzene ring.

(2) Nitration :**(3) Sulphonation :** Aniline reacts with fuming H_2SO_4 to give sulphanilic acid.(p-Amino-benzene sulphonic acid)

- This process is called baking.
- Sulphanilic acid is an important intermediate in the manufacturing of dyes and drugs.
- The compounds in which both proton donating & proton accepting groups present are called amphoteric (dipolar ion).

**(4) Catalytic hydrogenation :** Aniline undergoes hydrogenation in presence of Ni at high temp. to form cyclohexanamine.**Tests of Aniline:****(i) Carbylamine test :** Aniline gives carbylamine test or Isocyanide test.

(Bad smelling)

(ii) Dye test : Aniline is first diazotised. On adding alkaline solution. of β -naphthol to the diazotised product a red-orange dye is formed.**(iii)** On heating with bromine water, a white ppt. is formed.

Nitro benzene [C₆H₅NO₂]:

It is also called as artificial oil of bitter almonds or oil of mirbane as its odour is like that of bitter almonds.

General Methods of Preparation**(1) Lab method :****(2) From diazonium salt :****Physical Properties:**

- (i) Nitro benzene is light yellow oily liquid
- (ii) It has smell of bitter almonds
- (iii) It is steam volatile. Its vapours are poisonous in nature.
- (iv) It is heavier than water
- (v) Its B. P. is 211°C
- (vi) Smell of nitro benzene and benzaldehyde is same

Chemical Properties:

Nitrobenzene shows following chemical reactions –

- (1) Reactions due to NO₂ group.
- (2) Reactions due to benzene ring :
 - (A) Electrophilic substitution
 - (B) Nucleophilic substitution

**Test of Nitrobenzene:**

Mulliken Barker Test : Ethanolic solution of nitrobenzene is treated with zinc dust and NH_4Cl solution. The mixture is heated and filter in a test tube containing Tollen's reagent a grey or black precipitate (Ag mirror) is formed.

**Uses**

- (i) As a solvent
- (ii) In manufacture of aniline and azo dye

Beckmann rearrangement:

The Beckmann rearrangement is a rearrangement of an oxime functional group to substituted amides. The rearrangement has also been successfully performed on haloimines and nitrones. Cyclic oximes and haloimines yield lactams. This reaction has been named after the German chemist Ernst Otto Beckmann. The Beckmann rearrangement is often catalyzed by acid, however other reagents have been known to promote the rearrangement. These include tosylchloride, thionylchloride, phosphorus pentachloride, phosphorus pentoxide among others.

Reaction Mechanism:

The most common reaction mechanism of the Beckmann rearrangement consists generally of an alkyl migration anti-periplanar to the expulsion of a leaving group to form a nitrilium ion. This is followed by solvolysis to an imidate and then tautomerization to the amide.

Mechanism of Beckmann Rearrangement

Ex.

Mechanism:
